

## COMPARISON OF DIRECT-PUSH ANALYTICAL INSTRUMENTATION

Technology	Primary Uses	Advantages	Disadvantages	Media	Relative Cost
<b>ORGANIC SYSTEMS</b>					
<p>Laser Induced Fluorescence (LIF)</p> <p><b>TWO MAJOR SYSTEMS</b></p> <p>Site Characterization and Analysis Penetrometer System (SCAPS)</p> <p>Rapid Optical Screening Tool (ROST™)</p>	<p>Real-time, in-situ, field screening of hydrocarbons (specifically gasoline, diesel fuel, jet fuels, fuel oil, motor oil, grease, and coal tar based upon PAH content of each)</p>	<p>ROST™–System is available commercially through the Fugro corporation.</p> <p>Provides real-time chemical and geological information while in the field</p> <p>Capable of achieving 200 to 300 feet of pushes in a 10-hour work day</p> <p>Allows for small zones of contamination to be delineated that might be missed by conventional sampling protocols</p> <p>No cuttings are produced</p> <p>Push holes are filled as the probe is withdrawn</p> <p>Rods and probes are steam cleaned as they are withdrawn and fluids are containerized.</p>	<p>SCAPS–System is not available to private citizens or corporations.</p> <p>System is very complex and therefore, requires highly trained technicians (three-person crew and a geologist)</p> <p>Does not provide quantitative data.</p> <p>Limited to unconsolidated sediments and sites accessible to 20-ton CPT</p> <p>Interference--UV source may cause other substances to fluoresce (i.e. calcite, deicing agents and antifreeze additives, detergents, organic matter; etc.)</p> <p>Detection Limits are soil and fuel dependent (i.e. clays and fuels with low PAH content reduce delectability)</p>	<p>Soil and groundwater</p>	<p>Systems are usually procured as a service due to the system's complex nature.</p> <p>Purchase of a system incorporating the LIF is estimated at \$200,000-400,000, rental cost is estimated at \$4000/day.</p> <p>SCAPS–varies between \$12 and \$20 per foot (\$2,400 to \$6,000 per day)</p> <p>ROST™–under \$20 per foot (\$5,300 per day)</p> <p>LIF rental by itself costs range from \$2,000 to \$3,000 per day, which includes operators.</p>

### COMPARISON OF DIRECT-PUSH ANALYTICAL INSTRUMENTATION

Technology	Primary Uses	Advantages	Disadvantages	Media	Relative Cost
Mercury (Hg) Fluorescence	Site-specific relative screening of contamination levels (specifically jet fuels, diesel, unleaded gasoline, home heating and motor oil, coal tars and creosote)	<p>Cuts time needed to delineate the extent of hydrocarbon plumes from fuel spills or leaking storage tanks</p> <p>Can be adjusted for background fluorescence levels in soils with naturally occurring fluorescent substances</p> <p>Can provide real-time data and rapid three dimensional plume model without the time and expense of off-site data or post-processing of the data</p> <p>Analytical equipment is less costly than fiber optics</p>	<p>Environmental Conditions—output is decreased in cold temperatures, resulting in lower sensitivity</p> <p>Interference--the UV source may cause other substances to fluoresce (i.e. calcite, deicing agents and antifreeze additives, detergents, natural organic matter; etc.)</p> <p>Detection Limits—are soil and fuel dependent (i.e. clays and fuels with low PAH content reduce delectability)</p>	Soil and groundwater	<p>\$28,000 for complete FFD system (probe, data aquisition system, etc.) Does not include direct-push system (rods and platform)</p> <p>Rental options are approximately \$250.00/day or \$1,500/week</p>

### COMPARISON OF DIRECT-PUSH ANALYTICAL INSTRUMENTATION

Technology	Primary Uses	Advantages	Disadvantages	Media	Relative Cost
<p>Membrane Interface Probe (MIP)</p>	<p>Identification of various VOCs, depending on detector used</p> <p>Characterize subsurface soils and sediments with chemical contamination, mapping contaminant distribution and migration pathways</p>	<p>Provides information on contaminant distribution and migration pathways (with a conductivity probe)</p> <p>Can qualitatively identify specific compounds with the DSITMS detector</p> <p>Provides quantitative estimates of subsurface contamination distribution with DSITMS detector</p> <p>DSITMS configuration capable of meeting the precision and accuracy quality control performance criteria (EPA Method 624)</p>	<p>Can not differentiate VOCs using PID or FID detectors</p> <p>PID and FID detectors provide relative response only</p> <p>Results are less precise for vadose soils</p>	<p>Soil, sediment, and groundwater</p>	<p>Unit costs for direct-push probes with multi-detector MIP and soil conductivity capabilities are estimated at \$15/ft. or \$3000/day</p> <p>Purchase cost for the MIP unit itself ranges from \$19,000-\$22,000, including conductivity sensor</p>

### COMPARISON OF DIRECT-PUSH ANALYTICAL INSTRUMENTATION

Technology	Primary Uses	Advantages	Disadvantages	Media	Relative Cost
Thermal Desorption Sampler (TDS)	Characterization of shallow vadoze zone subsurface VOC contamination from fuel releases or chlorinated solvent releases	<p>Not affected by moisture until sample is saturated</p> <p>Has been certified as achieving detection thresholds for TCE and DCE comparable to those of EPA Method 8260A</p> <p>Is certified by Cal/EPA as a near real-time, qualitative to semi-quantitative, in situ subsurface field screening method for VOCs in the vadoze or capillary zone</p>	<p>Designed for on-site screening only</p> <p>Can only be used in the vadose zone</p> <p>When large lengths of line are used, water vapor from condensation in the transfer line can interfere with the analysis</p> <p>Exact soil sample weights and volume may vary significantly based on the type of soil, reducing accuracy</p>	Soil and soil gas	Approximately \$4,500 to \$5,500/day
Hydrosparge	Characterization sites with shallow groundwater VOC contamination	<p>Able to analyze VOCs without retrieving the direct-push rods and handling or packaging samples</p> <p>No sample preparation required</p> <p>Provides quick analysis time (2 to 3 minutes to analyze sample)</p>	<p>Only able to sample one discrete interval as the probe must be retracted to expose the sample and cannot be re-advanced</p> <p>Must make separate pushes to determine sampling intervals</p> <p>Interference of non-target VOCs</p>	Groundwater	<p>Purchase cost is approximately \$50,000</p> <p>Rental cost \$2,000 per month</p>

## COMPARISON OF DIRECT-PUSH ANALYTICAL INSTRUMENTATION

Technology	Primary Uses	Advantages	Disadvantages	Media	Relative Cost
<b>INORGANIC SYSTEMS</b>					
<p>X-ray Fluorescence (XRF)</p>	<p>Detection, identification, and delineation of heavy metal contaminants in the subsurface</p>	<p>Capable of detecting multiple analytes</p> <p>Allows for high-resolution delineation of subsurface metals contamination</p> <p>No waste generation.</p> <p>Provides quantitative analysis of a variety of heavy metals</p> <p>X-ray tubes—more powerful and achieve lower detection limits</p> <p>Radioisotope—generates a more consistent output and may deliver more precise and accurate results</p>	<p>Presence of radioactive source may require special licensing and shipping and handling procedures</p> <p>Matrix effect—physical and chemical properties of sample may effect analysis</p> <p>Susceptible to heterogeneity of contaminant distribution; no process for homogenizing soil before analysis</p> <p>Moisture above 20% may cause problems, but is manageable</p>	<p>Soil and sediment in unsaturated and saturated zones</p>	<p>Vary significantly</p>

### COMPARISON OF DIRECT-PUSH ANALYTICAL INSTRUMENTATION

Technology	Primary Uses	Advantages	Disadvantages	Media	Relative Cost
<p>Laser-Induced Breakdown Spectroscopy (LIBS)</p>	<p>Detection, identification, and delineation of heavy metal contaminants in the subsurface</p>	<p>Capable of detecting multiple analytes</p> <p>Allows for high-resolution delineation of subsurface metals contamination</p> <p>No waste generation.</p> <p>Achieves a lower detection limit than XRF</p> <p>Little or no sample preparation is required to obtain useful results</p> <p>The technique is readily portable to the field</p>	<p>Matrix effect—susceptible to heterogeneity of contaminant distribution; no process for homogenizing soil before analysis</p> <p>Does not perform well in saturated soils and sediments</p>	<p>Soil and sediment in unsaturated and capillary zones</p>	<p>Approximately \$4,500 to \$5,500/day</p>
<b>EXPLOSIVES SENSOR</b>					
<p>Explosives Sensor</p>	<p>Assessment of sites contaminated with energetic materials such as TNT, RDX, HMX, their manufacturing intermediates and subsequent breakdown products</p>	<p>Very sensitive to low levels of TNT in dry soils (0.5 ppm)</p> <p>Offers cost relief and time savings for large-scale sites</p>	<p>Provides total explosives concentrations - cannot differentiate among multiple explosives compounds</p> <p>Matrix interference—samples collected from nearly identical site locations and depths can have significantly different contamination levels</p>	<p>Soil and sediment</p>	<p>No costs are currently available. The system is precommercial.</p>
